

Introduction to Java for C++ Programmers

Segment - 3

JAC 444

Professor: Mahboob Ali

Objective

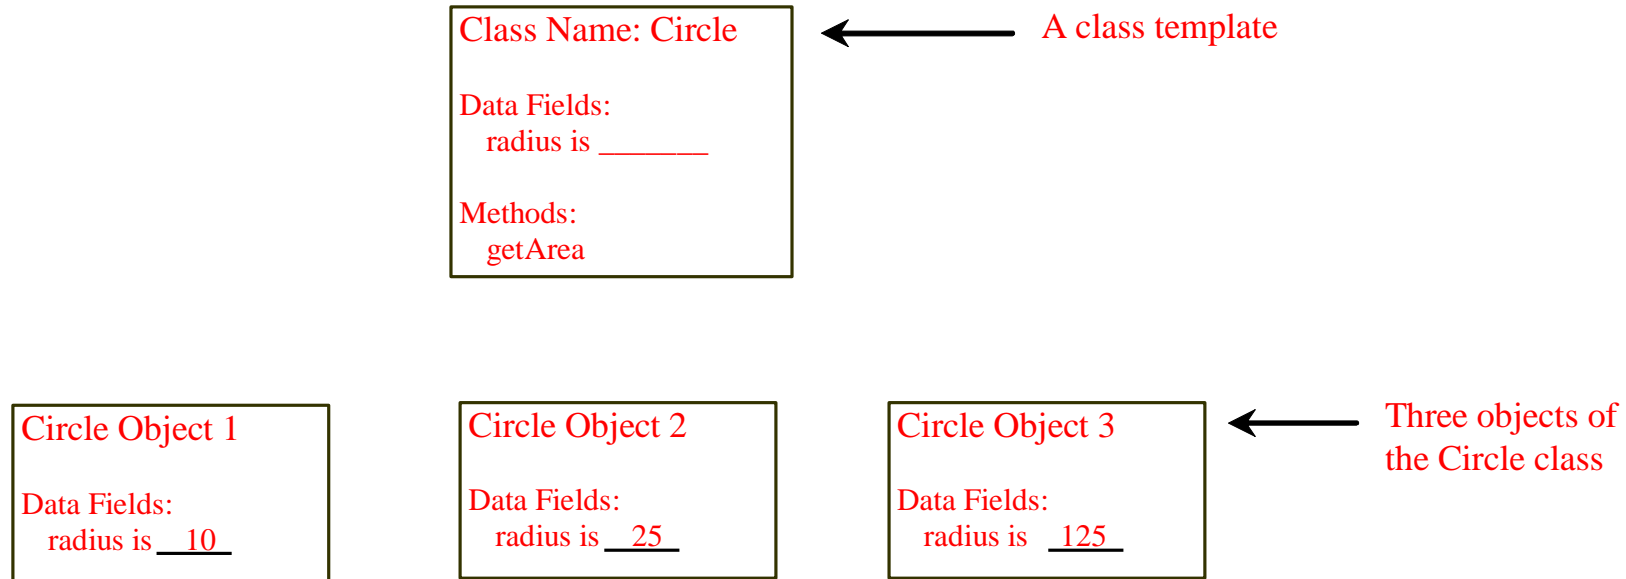

By the end of this segment students should be able to have understanding about:

- Object Oriented programming
- Java Objects
- Java Classes

Object Oriented Programming

- An *object*: represents an entity in the real world that can be distinctly identified.
- An object: has a unique identity, state, and behaviors.
- The *state*: of an object consists of a set of *data fields* (also known as *properties*) with their current values.
- The *behavior*: of an object is defined by a set of methods.

Objects

An object has both a state and behavior. The state defines the object, and the behavior defines what the object does.

Classes

Classes are constructs that define objects of the same type.

A Java class uses variables to define data fields and methods to define behaviors.

Additionally, a class provides a special type of methods, known as constructors, which are invoked to construct objects from the class.

Class Declaration

- The class declaration in Java has the following format:
 - **class ClassName { field(s)**
constructor(s)

method declaration(s) other class
declaration(s)
 - **}**
- The class contains **all the code you have to write**. Your code must be enclosed by curly braces.
- The object's' life cycle is determined by the elements of the class as following:
 1. Objects initializations – **Constructors**
 2. Objects states – **Fields**
 3. Class and its objects behaviors – **Methods**

UML Class Diagram

UML Class Diagram

← Class name

← Data fields

← Constructors and methods

← UML notation for objects

Constructors

Constructors are a special kind of methods that are invoked to construct objects.

```
Circle() { //No Argument Constructor  
  
}  
  
           //With Argument  
  
Circle(double newRadius) {  
    radius = newRadius;  
}
```

Constructors, cont.

- A constructor with **no parameters** is referred to as a ***no-arg constructor***.
- **Constructors must have the same name as the class itself.**
- **Constructors do not have a return type—not even void.**
- Constructors are invoked using the **new operator** when an object is created. Constructors play the role of **initializing objects**.

Default Constructor

- A class may be declared without constructors.
- In this case, a no-arg constructor with an empty body is implicitly declared in the class.
- This constructor, called a *default constructor*, is provided automatically *only if no constructors are explicitly declared in the class*.

Declaring/Creating Objects in a Single Step

```
ClassName objectRefVar = new ClassName();
```

Example:

Assign object reference Create an object

Circle myCircle = new Circle();

The diagram illustrates the components of the code line 'Circle myCircle = new Circle();'. A box is drawn around the expression 'new Circle();'. An arrow points from the text 'Assign object reference' to the variable 'myCircle'. Another arrow points from the text 'Create an object' to the boxed expression 'new Circle();'.

Accessing Objects

- Referencing the object's data:

`objectRefVar.data`

e.g., `myCircle.radius`

- Invoking the object's method:

`objectRefVar.methodName (arguments)`

e.g., `myCircle.getArea()`

Trace Code

```
Circle myCircle = new Circle(5.0);  
SCircle yourCircle = new Circle();  
yourCircle.radius = 100;
```

Declare myCircle

myCircle

no value

Trace Code, cont.

```
Circle myCircle = new Circle(5.0);
```

```
Circle yourCircle = new Circle();
```

```
yourCircle.radius = 100;
```

myCircle **no value**

Create a
circle

Trace Code, cont.

```
Circle myCircle = new Circle(5.0);  
Circle yourCircle = new Circle();  
yourCircle.radius = 100;
```

Assign object reference to
myCircle

myCircle **reference value**

: Circle

radius: 5.0

Trace Code, cont.

```
Circle myCircle = new Circle(5.0);
```

```
Circle yourCircle = new Circle();
```

```
yourCircle.radius = 100;
```

myCircle **reference value**

yourCircle **no value**

Trace Code, cont.

```
Circle myCircle = new Circle(5.0);
```

```
Circle yourCircle = new Circle();
```

```
yourCircle.radius = 100;
```

myCircle **reference value**

yourCircle **no value**

Create a new
Circle object

Trace Code, cont.

```
Circle myCircle = new Circle(5.0);
```

```
Circle yourCircle = new Circle();
```

```
yourCircle.radius = 100;
```

myCircle **reference value**

yourCircle **reference value**

Assign object reference
to yourCircle

Trace Code, cont.

```
Circle myCircle = new Circle(5.0);
```

```
Circle yourCircle = new Circle();
```

```
yourCircle.radius = 100;
```

myCircle **reference value**

yourCircle **reference value**

Change radius in
yourCircle

Math.methodName(arguments) e.g., Math.pow(3,2)

Circle1.getArea() ?

- Methods used in Math class are static methods, which are defined using the static keyword.
- However, getArea() is non-static. It must be invoked from an object using

objectRefVar.methodName(arguments) (e.g., myCircle.getArea()).

Copying Variables of Primitive Data Types and Object Types

Primitive type assignment $i = j$

Before:

i 1

j 2

After:

i 2

j 2

Primitive type assignments? $i = j$
Object type assignments? $c1 = c2$

Object type assignment $c1 = c2$

Java has
automatic Garbage
Collection

What will happen to this?

Before:

After:
